

What is Pagination in backend?

Pagination means splitting large amounts of data into smaller, more manageable 'pages' instead of returning everything at once.

Example: If you have 10,000 products, you don't want to send all of them to the frontend in a single API call (slow + memory heavy). Instead, you send 10 products per page.

The client can then request:

Page 1 → Products 1–10

Page 2 → Products 11–20

...and so on.

Why is Pagination important?

- Improves performance (less data sent per request).
- Reduces server & client memory usage.
- Better user experience (loading fast).
